- Use LaTeX to write-up your solutions (in the solution blocks of the source LaTeX file of this assignment), and submit the resulting single pdf file at GradeScope by the suggested due date. Within GradeScope, indicate the page number where your solution to each question starts, else we won't be able to grade it!
(**Note:** Due to the COVID situation and related institute mandates, there won't be late submission penalties to give students with poor internet access or other difficulties flexibility in completing assignments. If you do have proper internet access and other facilities, we highly recommend you to submit your solutions by the suggested due date to avoid being overwhelmed by all your works when institute reopens.)
- Collaboration is encouraged, but all write-ups must be done individually and independently, and mention your collaborator(s) if any. Same rules apply for codes written for any programming assignments (i.e., write your own code; we will run plagiarism checks on codes).
- If you have referred a book or any other online material for obtaining a solution, please cite the source. Again don't copy the source *as is* - you may use the source to understand the solution, but write-up the solution in your own words.

1. (14 points) [CIRCULAR CLEANUP!] [from Stanford's Stat375 course]
We want to implement a simple image segmentation/denoising algorithm based on Cluster Graph Belief Propagation (aka CG-BP or Loopy-BP) inference. The algorithm will take as input a $n \times n$ binary image encoded by the $0-1$ matrix:

$$\underline{y} = \{y_i \in \{0,1\} : i = (i_1, i_2) \in [n] \times [n]\},$$

and return a $0-1$ matrix:

$$\underline{\hat{x}} = \{\hat{x}_i \in \{0,1\} : i = (i_1, i_2) \in [n] \times [n]\}.$$

We expect nearby entries in $\hat{x}$ to have similar values; so to accomplish this goal, we introduce a graphical model of the form:

$$\mu(\underline{x}, \underline{y}) = \frac{1}{Z} \left(\prod_{i \in [n-1] \times [n]} \psi\left(x_i, x_{i+\hat{d}}\right) \right) \left(\prod_{i \in [n] \times [n-1]} \psi\left(x_i, x_{i+\hat{r}}\right) \right) \left(\prod_{i \in [n] \times [n]} \phi\left(x_i, y_i\right) \right),$$

where for $i = (i_1, i_2)$, we let $i + \hat{d} = (i_1 + 1, i_2)$ and $i + \hat{r} = (i_1, i_2 + 1)$. The compatibility functions are given in matrix form by:

$$\psi(\cdot,\cdot) = \begin{pmatrix} 1+\theta & 1-\theta \\ 1-\theta & 1+\theta \end{pmatrix}, \text{ and}$$

$$\phi(\cdot,\cdot) = \begin{pmatrix} 1+\gamma & 1-\gamma \\ 1-\gamma & 1+\gamma \end{pmatrix}$$

for some $\theta \in [0,1]$ and $\gamma \in [0,1]$.

(a) (3 points) Write the CG-BP (sum-product and max-product) message update rules of this model, assuming a Bethe Cluster Graph (Factor Graph) representation.
sol: There are six types of messages. For messages whose indices crosses boundary then that message can be taken as 1. The cluster considered are $\{x_{ij}\}, \{y_{ij}\}, \{x_{ij}, x_{ij+1}\}, \{x_{ij+1}\}, \{x_{ij}, y_{ij}\}$
the sum product message updates are as follows:

$$m^{t+1}_{\{x_{ij},x_{ij+1}\}\to\{x_{ij}\}}(x_{ij}) = \Sigma_{x_{ij+1}} \psi(x_{ij}, x_{ij+1}) m^{t}_{\{x_{ij+1}\}\to\{x_{ij},x_{ij+1}\}}(x_{ij+1})$$

$$m^{t+1}_{\{x_{ij}\}\to\{x_{ij},x_{ij+1}\}}(x_{ij}) = m^{t}_{\{x_{ij},x_{i+1j}\}\to\{x_{ij}\}}(x_{ij}) m^{t}_{\{x_{ij},x_{i-1j}\}\to\{x_{ij}\}}(x_{ij}) m^{t}_{\{x_{ij},x_{ij-1}\}\to\{x_{ij}\}}(x_{ij}) m^{t}_{\{x_{ij},y_{ij}\}\to\{x_{ij}\}}(x_{ij})$$

$$m^{t+1}_{\{x_{ij},y_{ij}\}\to\{x_{ij}\}}(x_{ij}) = \phi(x_{ij}, y_{ij}) m^{t}_{\{y_{ij}\}\to\{x_{ij},y_{ij}\}}(y_{ij})$$

$$m^{t+1}_{\{x_{ij}\}\to\{x_{ij},y_{ij}\}}(x_{ij}) = m^{t}_{\{x_{ij},x_{i+1j}\}\to\{x_{ij}\}}(x_{ij}) m^{t}_{\{x_{ij},x_{i-1j}\}\to\{x_{ij}\}}(x_{ij}) m^{t}_{\{x_{ij},x_{ij-1}\}\to\{x_{ij}\}}(x_{ij}) m^{t}_{\{x_{ij},x_{ij+1}\}\to\{x_{ij}\}}(x_{ij})$$

$$m^{t+1}_{\{x_{ij},y_{ij}\}\to\{y_{ij}\}}(y_{ij}) = \Sigma_{x_{ij}} \phi(x_{ij}, y_{ij}) m^{t}_{\{x_{ij}\}\to\{x_{ij},y_{ij}\}}(x_{ij})$$

$$m^{t+1}_{\{y_{ij}\}\to\{x_{ij},y_{ij}\}}(y_{ij}) = 1$$

The max product message updates are as follows:

$$m^{t+1}_{\{x_{ij},x_{ij+1}\}\to\{x_{ij}\}}(x_{ij}) = \max_{x_{ij+1}} \psi(x_{ij}, x_{ij+1}) m^{t}_{\{x_{ij+1}\}\to\{x_{ij},x_{ij+1}\}}(x_{ij+1})$$

$$m^{t+1}_{\{x_{ij}\}\to\{x_{ij},x_{ij+1}\}}(x_{ij}) = m^{t}_{\{x_{ij},x_{i+1j}\}\to\{x_{ij}\}}(x_{ij}) m^{t}_{\{x_{ij},x_{i-1j}\}\to\{x_{ij}\}}(x_{ij}) m^{t}_{\{x_{ij},x_{ij-1}\}\to\{x_{ij}\}}(x_{ij}) m^{t}_{\{x_{ij},y_{ij}\}\to\{x_{ij}\}}(x_{ij})$$

$$m^{t+1}_{\{x_{ij},y_{ij}\}\to\{x_{ij}\}}(x_{ij}) = \phi(x_{ij}, y_{ij}) m^{t}_{\{y_{ij}\}\to\{x_{ij},y_{ij}\}}(y_{ij})$$

$$m^{t+1}_{\{x_{ij}\}\to\{x_{ij},y_{ij}\}}(x_{ij}) = m^{t}_{\{x_{ij},x_{i+1j}\}\to\{x_{ij}\}}(x_{ij}) m^{t}_{\{x_{ij},x_{i-1j}\}\to\{x_{ij}\}}(x_{ij}) m^{t}_{\{x_{ij},x_{ij-1}\}\to\{x_{ij}\}}(x_{ij}) m^{t}_{\{x_{ij},x_{ij+1}\}\to\{x_{ij}\}}(x_{ij})$$

$$m^{t+1}_{\{x_{ij},y_{ij}\}\to\{y_{ij}\}}(y_{ij}) = \max_{x_{ij}} \phi(x_{ij}, y_{ij}) m^{t}_{\{x_{ij}\}\to\{x_{ij},y_{ij}\}}(x_{ij})$$

$$m^{t+1}_{\{y_{ij}\}\to\{x_{ij},y_{ij}\}}(y_{ij}) = 1$$

(b) (2 points) Provide a concise pseudocode that specifically shows how to initialize and schedule the message updates from above, in order to achieve the goal of constructing a denoised image $\underline{\hat{x}}$ from a noisy image $\underline{y}$.
sol:

- First we index all the clusters in the Bethe cluster graph constructed from the input. Next we store all the edges in the graph in both directions, these correspond to the messages
- We initialize all the messages of edges to 1.
- A list of length equals number of edges is made whose entries are randomly chosen edge indices. The messages of edges are updated using max product equations given above in order of edge indices from the list constructed. This is repeated for 10 iterations.
- We multiply all the messages received at cluster X_i and take argmax for $\hat{x}_i$ value

(c) (5 points) Implement the pseudocode and test your program on a noisy image $\underline{y}$ obtained as follows: construct a 100×100 binary matrix $\underline{x}$ corresponding to a circle of radius 25 with center in position $(50, 50)$, and add noise by flipping each entry independently with probability p to obtain $\underline{y}$. Run the program on three images generated with $p = 0.1,\ 0.2$, and 0.3. Display the corresponding images (input and output), together with the values of parameters (θ, γ) used. (Note: Please also provide your denoising code that takes input/output images as comma-separated ASCII files with three columns $(i_1, i_2, value_{(i_1,i_2)})$ to help check your work).

```

(d) (4 points) Count the number of positions at which the estimated $\underline{\hat{x}}$ matches the noise-free circle $\underline{x}$, and average this number across many input instances/runs of your program. Report this average performance for a few values of (θ, γ), and comment on which choice offered the best performance. If you wanted to be more systematic to find the best value of (θ, γ) among all values it takes (instead of trying only a few values and taking its best), briefly mention what approach would you take?

sol:

for p = 0.1 , runs = 10, iters = 10		
θ-value	γ-value	Average count
0.9	0.9	9976.2
0.9	0.8	9979.6
0.9	0.7	9978.2
0.7	0.9	9973.1
0.2	0.1	9976.7

for p = 0.2 , runs = 10, iters = 20		
θ-value	γ-value	Average count
0.9	0.9	9948.4
0.9	0.8	9955.4
0.9	0.7	9950.1
0.7	0.9	9922.3
0.2	0.1	9952.0

for p = 0.3 , runs = 10, iters = 20		
θ-value	γ-value	Average count
0.9	0.9	9890.1
0.9	0.8	9907.5
0.9	0.7	9906.1
0.7	0.9	9684.6
0.2	0.1	9906.6

- The value of θ should be greater than or equal to the value of γ as θ decides the nature of the image and γ decides closeness to noisy image.
- The values of both θ and γ should be closer to 1 but not closer to 0. If γ is closer to 0, then reconstructed image will tend to be all zeros.

- Fixing θ to be closer to 1. The value of γ is decreased relative to θ to get ideal their ideal values.

2. (12 points) [APPROXIMATE INFERENCE ON RBMS] Consider a Markov network over m hidden $\{0,1\}$ variables H_i and n visible $\{0,1\}$-variables V_j. Let the joint distribution of this model be defined as:
$P(H = h, V = v) = \frac{1}{Z} \exp(h^T W v + c^T v + b^T h)$,
where $W \in \mathbb{R}_{m,n}, c \in \mathbb{R}_n n, b \in \mathbb{R}_m$ are the parameters of the model.

   This is called a *Restricted* Boltzmann Machine or RBM since the edges in the Markov network are restricted to be between a hidden node and a visible node (and specifically no edges are allowed between any two hidden nodes or any two visible nodes; note that this property makes RBMs, specifically stacking of multiple RBMs, have interesting links to generative deep learning models with varied applications). To do approximate inference on a RBM model, we could employ any of these methods. Write down their update equations and simplify your terms as much as possible.

   (a) (3 points) Derive standard Gibbs sampling updates of this RBM model (specifically, provide two update equations, one for sampling each H_i given all other variables and another for sampling V_j given all other variables). Report the running time complexity per update and per epoch (an epoch comprises update of every variable in the model).
   sol:

$$\begin{aligned}
p(H_i = h_i \mid H_{-i} = h_{-i}, V = v) &= \frac{p(H = h, V = v)}{\Sigma_{h_i} p(H = h, V = v)} \\
&= \frac{\exp(h_i b_i + h_i W_{i,:} v)(\prod_{k \neq i} \exp(h_k b_k + h_k W_{k,:} v)) \exp(c^T v)}{\exp \Sigma_{h_i} (h_i b_i + h_i W_{i,:} v)(\prod_{k \neq i} \exp(h_k b_k + h_k W_{k,:} v)) \exp(c^T v)} \\
&= \frac{\exp(h_i b_i + h_i W_{i,:} v)}{\exp \Sigma_{h_i} (h_i b_i + h_i W_{i,:} v)} \\
p(H_i = 1 \mid H_{-i} = h_{-i}, V = v) &= \frac{\exp(b_i + W_{i,:} v)}{\exp(b_i + W_{i,:} v) + 1} \\
p(H_i = 0 \mid H_{-i} = h_{-i}, V = v) &= \frac{1}{\exp(b_i + W_{i,:} v) + 1}
\end{aligned}$$

   The running time complexity per update is O(n) for calculating $W_{i,:} v$. For an epoch running

time complexity is O(mn)

$$p(V_j = v_j \mid V_{-j} = v_{-j}, H = h) = \frac{p(H = h, V = v)}{\Sigma_{v_j} p(H = h, V = v)}$$
$$= \frac{\exp(v_j h^T W_{:,j} + c_j v_j)(\prod_{k \neq j} \exp v_k h^T W_{:,k} + c_k v_k) \exp b^T h}{\Sigma_{v_j} \exp(v_j h^T W_{:,j} + c_j v_j)(\prod_{k \neq j} \exp v_k h^T W_{:,k} + c_k) \exp b^T h}$$
$$= \frac{\exp(v_j h^T W_{:,j} + c_j v_j)}{\Sigma_{v_j} \exp(v_j h^T W_{:,j} + c_j v_j)}$$
$$p(V_j = 1 \mid V_{-j} = v_{-j}, H = h) = \frac{\exp(h^T W_{:,j} + c_j)}{\exp(h^T W_{:,j} + c_j) + 1}$$
$$p(V_j = 0 \mid V_{-j} = v_{-j}, H = h) = \frac{1}{\exp(h^T W_{:,j} + c_j) + 1}$$

The running time complexity per update is O(m) for calculating $h^T W_{:,j}$. For an epoch running time complexity is O(nm)

(b) (3 points) Derive Block Gibbs sampling updates of this RBM model. Consider two blocks (one for all hidden node, and another for all visible nodes). Report the running time per block update - can you make this update as efficient as possible (i.e., make the running time per epoch the same as one epoch of standard Gibbs sampling) by exploiting the restricted structure of the RBM network? Can you parallelize each block update and what will be the resulting running time?
sol:

$$p(H = h \mid V = v) = \frac{p(H = h, V = v)}{\Sigma_h p(H = h, V = v)}$$
$$= \frac{\prod_{k=1}^{m} \exp(h_k b_k + h_k W_{k,:} v) \exp(c^T v)}{\prod_{k=1}^{m} \Sigma_{h_k} \exp(h_k b_k + h_k W_{k,:} v) \exp(c^T v)}$$
$$= \prod_{k=1}^{m} [\frac{\exp(b_k + W_{k,:} v)}{\exp(b_k + W_{k,:} v) + 1}]^{h_k} [\frac{1}{\exp(b_k + W_{k,:} v) + 1}]^{1-h_k}$$

The running time complexity is O(mn). If we parallelize then running time complexity would be O(n) assuming all m computation are done at the same instant.

$$p(V = v \mid H = h) = \frac{p(H = h, V = v)}{\Sigma_v p(H = h, V = v)}$$
$$= \frac{\prod_{k=1}^{n} \exp(v_k c_k + v_k h^T W_{:,k}) \exp(b^T h)}{\prod_{k=1}^{n} \Sigma_{h_k} \exp(v_k c_k + v_k h^T W_{:,k}) \exp(b^T h)}$$
$$= \prod_{k=1}^{n} [\frac{\exp(c_k + h^T W_{:,k})}{\exp(c_k + h^T W_{:,k}) + 1}]^{v_k} [\frac{1}{\exp(c_k + h^T W_{:,k}) + 1}]^{1-v_k}$$

The running time complexity is O(mn). If we parallelize then running time complexity would be O(m) assuming all n computation are done at the same instant.

(c) (3 points) Derive the Naïve Mean Field updates of this RBM model. Describe how you can use these updates (after convergence to their fixed-point values) to approximate, specifically lower-bound, the partition function Z?
sol:

$$\begin{aligned}
Q_{H_i}(h_i) &\propto \exp\left(E_Q[\ln(p(H=h,V=v)) \mid H_i = h_i]\right) \\
&\propto \exp\left(E_Q[\ln(\exp(h_i b_i + h_i W_{i,:} v) \prod_{k \neq i} \exp(h_k b_k + h_k W_{k,:} v) \exp(c^T v)) \mid H_i = h_i]\right) \\
&\propto \exp\left(E_{Q_{-H_i}}[\ln(\exp(h_i b_i + h_i W_{i,:} v)]\right) \\
&\propto \exp\left(E_{Q_{-H_i}}[h_i b_i + h_i W_{i,:} v]\right) \\
&\propto \exp\left(h_i b_i + E_{Q_V}[h_i W_{i,:} v]\right) \\
&\propto \exp\left(h_i b_i + h_i W_{i,:} Q_V(v=1)\right)
\end{aligned}$$

$Q_V(v=1)$ is a column vector with each entry given by $Q_{V_i}(v_i = 1)$

$$\begin{aligned}
Q_{H_i}(h_i = 1) &= \frac{\exp\left(b_i + W_{i,:} Q_V(v=1)\right)}{\exp\left(b_i + W_{i,:} Q_V(v=1)\right) + 1} \\
Q_{H_i}(h_i = 0) &= \frac{1}{\exp\left(b_i + W_{i,:} Q_V(v=1)\right) + 1}
\end{aligned}$$

$$\begin{aligned}
Q_{V_i}(v_i) &\propto \exp\left(E_Q[\ln(p(H=h,V=v)) \mid V_i = v_i]\right) \\
&\propto \exp\left(E_Q[\ln(\exp(v_i c_i + v_i h^T W_{:,i}) \prod_{k \neq i} \exp(c_k v_k + v_k h^T W_{:,k}) \exp(b^T h)) \mid V_i = v_i]\right) \\
&\propto \exp\left(E_{Q_{-V_i}}[\ln(\exp(v_i c_i + v_i h^T W_{:,i})]\right) \\
&\propto \exp\left(E_{Q_{-V_i}} v_i c_i + v_i h^T W_{:,i}]\right) \\
&\propto \exp\left(v_i c_i + E_{Q_H}[v_i h^T W_{:,i}]\right) \\
&\propto \exp\left(v_i c_i + v_i Q_H(h=1)^T W_{:,i}\right)
\end{aligned}$$

$Q_H(h=1)$ is a column vector with each entry given by $Q_{H_i}(h_i = 1)$

$$\begin{aligned}
Q_{V_i}(v_i = 1) &= \frac{\exp\left(c_i + Q_H(h=1)^T W_{:,i}\right)}{\exp\left(c_i + Q_H(h=1)^T W_{:,i}\right) + 1} \\
Q_{V_i}(v_i = 0) &= \frac{1}{\exp\left(c_i + Q_H(h=1)^T W_{:,i}\right) + 1}
\end{aligned}$$

We know that $E_Q \ln(\tilde{P}(X)) + H_Q(X)$ is the lower bound for $\ln Z$ considering X to be collection

of r.vs H_i, V_j. Each term can be calculated as shown below.

$$\begin{aligned}
E_Q \ln(\tilde{P}(X)) &= E_Q[h^T W v + b^T h + c^T v] \\
&= E_{Q_H}(h)^T W E_{Q_V}(v) + b^T E_{Q_H}(h) + c^T E_{Q_V}(v) \\
&= Q_H(h=1)^T W Q_V(v=1) + b^T Q_H(h=1) + c^T Q_V(v=1)
\end{aligned}$$

$$\begin{aligned}
H_Q(X) &= \Sigma_{k=1}^{m} H_{Q_{H_k}}(h_k) + \Sigma_{k=1}^{n} H_{Q_{V_k}}(v_k) \\
H_{Q_{H_k}}(h_k) &= -Q_{H_k}(h_k=1)\log(Q_{H_k}(h_k=1)) - Q_{H_k}(h_k=0)\log(Q_{H_k}(h_k=0)) \\
H_{Q_{V_k}}(v_k) &= -Q_{V_k}(v_k=1)\log(Q_{V_k}(v_k=1)) - Q_{V_k}(v_k=0)\log(Q_{V_k}(v_k=0))
\end{aligned}$$

(d) (3 points) Derive the Loopy BP updates of this RBM model, again assuming a Bethe Cluster Graph (Factor Graph) representation. Express the maximized FFEF (Factored Free Energy Functional, aka Bethe free energy approximation) in terms of the converged Loopy BP messages. While this FFEF is not a theoretical lower bound for Z, argue heuristically when it can be used to approximate Z.
sol: The clusters will be of the form $\{H_i\}, \{V_j\}, \{H_i, V_j\}$ Message updates are as follows:

$$m^{t+1}_{\{H_i\}\to\{H_i,V_j\}}(h_i) = \exp(b_i h_i) \prod_{k\neq j, k=1}^{n} m^{t}_{\{H_i,V_k\}\to\{H_i\}}(h_i)$$

$$m^{t+1}_{\{H_i,V_j\}\to\{H_i\}}(h_i) = \Sigma_{v_j} m^{t}_{\{V_j\}\to\{H_i,V_j\}}(v_j)\exp(w_{ij} h_i v_j)$$

$$m^{t+1}_{\{V_j\}\to\{H_i,V_j\}}(v_j) = \exp(c_j v_j) \prod_{k\neq i, k=1}^{m} m^{t}_{\{H_k,V_j\}\to\{V_j\}}(v_j)$$

$$m^{t+1}_{\{H_i,V_j\}\to\{V_j\}}(v_j) = \Sigma_{h_i} m^{t}_{\{H_i\}\to\{H_i,V_j\}}(h_i)\exp(w_{ij} h_i v_j)$$

The converged messages can be used to compute marginals as follows:

$$Q_{H_i}(hi) = \exp(h_i b_i) \prod_{k=1}^{n} m_{\{H_i,V_k\}\to\{H_i\}}(h_i)$$

$$Q_{V_j}(v_j) = \exp(c_j v_j) \prod_{k=1}^{m} m_{\{H_k,V_j\}\to\{V_j\}}(v_j)$$

$$Q_{H_i V_j}(h_i, v_j) = m^{t+1}_{\{H_i\}\to\{H_i,V_j\}}(h_i) m^{t+1}_{\{V_j\}\to\{H_i,V_j\}}(v_j)\exp(w_{ij} h_i v_j)$$

FFEF is given by $\Sigma_{i\in C}E_{\beta_i}[\ln(\psi_i(C_i))] + \Sigma_{i\in C}H_{\beta_i} - \Sigma_{(i,j)\in edges}H_{\mu_{i,j}}$
First term in FFEF calcualted as:

$$\begin{aligned}\Sigma_{i\in C}E_{\beta_i}[\ln(\psi_i(C_i))] &= \Sigma_{i=1}^{m}E_{H_i}[b_i h_i] + \Sigma_{j=1}^{n}E_{V_j}[c_j v_j] + \Sigma_{i=1}^{m}\Sigma_{j=1}^{n}E_{H_iV_j}[h_i w_{ij} v_j] \\ &= \Sigma_{i=1}^{m} b_i Q_{H_i}(h_i = 1) + \Sigma_{j=1}^{n} c_j Q_{V_j}(v_j = 1) + \Sigma_{i=1}^{m}\Sigma_{j=1}^{n} w_{ij} Q_{H_i}(h_i = 1) Q_{V_j}(v_j = 1)\end{aligned}$$

We need the following equations to calculate other terms in FFEF:

$$H_{H_i} = \Sigma_{h_i=0}^{1} - Q_{H_i}(h_i)\log(Q_{H_i}(h_i))$$

$$H_{V_i} = \Sigma_{v_j=0}^{1} - Q_{V_j}(v_j)\log(Q_{V_j}(v_j))$$

$$H_{H_iV_j} = \Sigma_{h_i=0}^{1}\Sigma_{v_j=0}^{1} - Q_{H_i}(h_i)Q_{V_j}(v_j)\log(Q_{H_i}(h_i)Q_{V_j}(v_j))$$

Second term in FFEF:

$$\Sigma_{i\in C}H_{\beta_i} = \Sigma_{i=1}^{m}H_{H_i} + \Sigma_{j=1}^{n}H_{V_j} + \Sigma_{i=1}^{m}\Sigma_{j=1}^{n}H_{H_iV_j}$$

Third term in FFEF:

$$\Sigma_{(i,j)\in edges}H_{\mu_{i,j}} = n\Sigma_{i=1}^{m}H_{H_i} + m\Sigma_{j=1}^{n}H_{V_j}$$

If m or n is equal to 1, then the cluster graph reduces to a tree. FFEF can then be considered as lower bound to parition function.

3. (14 points) [DIRICHLET TO OUR RESCUE] We would like to survey the rapidly accumulating research literature on the ongoing COVID-19 outbreak (for instance, a corpus dataset called CORD-19 collects 50,000+ scholarly articles about COVID-19), so as to identify and potentially address gaps in our current knowledge about the virus. To save time, you only want to have a glance at important topics and words in an article. You decided to develop a bot called Dirichlet() that can summarize you the topics present in a research article (along with the important words in varying proportions describing that topic), with no prior knowledge about what topics to look for (which suits us well as someone new to virology or epidemiology). Dirichlet() uses Latent Dirichlet Allocation (LDA) on the whole corpus of articles/documents to achieve this topic modelling task. This question is only on the theory of approximate inference in LDA (though in normal course offerings, we would also have you implement LDA using tools like gensim to analyse a corpus; interestingly, results from LDA analysis of a COVID-19 corpus is depicted here).

   The LDA model can be viewed as a BN with these (local) conditional probabilities:

$$\phi_k \sim Dirichlet(\beta) \tag{1}$$

$$\theta_i \sim Dirichlet(\alpha) \tag{2}$$

$$z_{ji} \mid \theta_i \sim Categorical(\theta_i) \tag{3}$$

$$d_{ji} \mid z_{ji}, \phi_{z_{ji}} \sim \text{Categorical}(\phi_{z_{ji}}) \tag{4}$$

Here j is the index for words ($d_i = \{d_{1i}, ..., d_{Ni}\}$), i is the index for documents, and k is the index for topics. Also, we use the following notation: $N_{wki} = |\{j : d_{ji} = w, z_{ji} = k\}|$ (total number of times the word w is assigned to the topic k in document i), $N_{ki} = \sum_{w \in \text{Vocabulary}} N_{wki}$, and $N_{wk} = \sum_i N_{wki}$. We use superscript (-ji) (e.g. N_{wki}^{-ji}) to indicate the corresponding word d_{ji} in document i is not counted in N_{wki}. By the BN chain rule, the joint distribution is thus given by:

$$\begin{aligned} P(d, z, \theta, \phi \mid \alpha, \beta) &= \left(\prod_k P(\phi_k \mid \beta)\right) \prod_i P(\theta_i \mid \alpha) \prod_j P(z_{ji} \mid \theta_i) P(d_{ji} \mid z_{ji}, \phi) \\ &= \left(\prod_k \frac{1}{Z(\beta)} \prod_w \phi_{kw}^{\beta_w - 1}\right) \prod_i \left(\frac{1}{Z(\alpha)} \prod_k \theta_{ik}^{\alpha_k - 1}\right) \prod_j \theta_{i, z_{ji}} \phi_{z_{ji}, d_{ji}}, \end{aligned}$$

where $Z(\alpha)$ (or $Z(\beta)$) denotes the normalizing constant of the corresponding Dirichlet distribution (based on $\Gamma(.)$ functions). Assume the hyperparameters α, β are fixed and known.

(a) (3 points) Write down $P(d \mid z, \beta)$ and $P(z \mid \alpha)$ in terms of functions of $\{N_{wk}, \beta\}$ and $\{N_{ki}, \alpha\}$ respectively. (Hint: Integrate out ϕ and θ respectively; you may find Section 4 of this writeup on Dirichlet-Categorical compound distbn. helpful.)
sol:

$$\begin{aligned} p(z \mid \alpha) &= \int p(z \mid \theta) p(\theta \mid \alpha) d\theta \\ &= \int \prod_{i=1}^{M} p(z_i \mid \theta_i) p(\theta_i \mid \alpha) d\theta \\ &= \prod_{i=1}^{M} \int p(z_i \mid \theta_i) p(\theta_i \mid \alpha) d\theta_i \\ &= \prod_{i=1}^{M} \int \frac{\Gamma(\Sigma_{k=1}^{K} \alpha_k)}{\prod_{k=1}^{K} \Gamma(\alpha_k)} \prod_{k=1}^{K} \theta_{ik}^{\alpha_k - 1} \prod_{j=1}^{N_i} \theta_{i z_{ji}} d\theta_i \\ &= \prod_{i=1}^{M} \int \frac{\Gamma(\Sigma_{k=1}^{K} \alpha_k)}{\prod_{k=1}^{K} \Gamma(\alpha_k)} \prod_{k=1}^{K} \theta_{ik}^{\alpha_k - 1} \prod_{k=1}^{K} \theta_{ik}^{N_{ki}} d\theta_i \\ &= \prod_{i=1}^{M} \int \frac{\Gamma(\Sigma_{k=1}^{K} \alpha_k)}{\prod_{k=1}^{K} \Gamma(\alpha_k)} \prod_{k=1}^{K} \theta_{ik}^{\alpha_k + N_{ki} - 1} d\theta_i \\ &= \prod_{i=1}^{M} \frac{\Gamma(\Sigma_{k=1}^{K} \alpha_k)}{\prod_{k=1}^{K} \Gamma(\alpha_k)} \frac{\prod_{k=1}^{K} \Gamma(N_{ki} + \alpha_k)}{\Gamma(\Sigma_{k=1}^{K} N_{ki} + \alpha_k)} \int \frac{\Gamma(\Sigma_{k=1}^{K} N_{ki} + \alpha_k)}{\prod_{k=1}^{K} \Gamma(N_{ki} + \alpha_k)} \prod_{k=1}^{K} \theta_{ki}^{\alpha_k + N_{ki} - 1} d\theta_i \\ &= \prod_{i=1}^{M} \frac{\Gamma(\Sigma_{k=1}^{K} \alpha_k)}{\prod_{k=1}^{K} \Gamma(\alpha_k)} \frac{\prod_{k=1}^{K} \Gamma(N_{ki} + \alpha_k)}{\Gamma(\Sigma_{k=1}^{K} N_{ki} + \alpha_k)} \end{aligned}$$

$$
\begin{aligned}
p(d \mid z, \beta) &= \int p(\phi \mid \beta) p(d \mid \phi, z) d\phi \\
&= \int \prod_{k=1}^{K} p(\phi_k \mid \beta) \prod_{i=1}^{M} \prod_{j=1}^{N_i} p(d_{ji} \mid \phi_{ji}) d\phi \\
&= \prod_{k=1}^{K} \int p(\phi_k \mid \beta) \prod_{i=1}^{M} \prod_{j=1}^{N_i} p(d_{ji} \mid \phi_{ji}) d\phi_k \\
&= \prod_{k=1}^{K} \int \frac{\Gamma(\Sigma_{w=1}^{J} \beta_w)}{\Sigma_{w=1}^{J} \Gamma(\beta_w)} \prod_{w=1}^{J} \phi_{kw}^{\beta_w - 1} \prod_{i=1}^{M} \prod_{j=1}^{N_i} \phi_{z_{ji} d_{ji}} d\phi_k \\
&= \prod_{k=1}^{K} \int \frac{\Gamma(\Sigma_{w=1}^{J} \beta_w)}{\Sigma_{w=1}^{J} \Gamma(\beta_w)} \prod_{w=1}^{J} \phi_{kw}^{\beta_w - 1} \prod_{w=1}^{J} \phi_{kw}^{N_{wk}} d\phi_k \\
&= \prod_{k=1}^{K} \int \frac{\Gamma(\Sigma_{w=1}^{J} \beta_w)}{\Sigma_{w=1}^{J} \Gamma(\beta_w)} \prod_{w=1}^{J} \phi_{kw}^{\beta_w + N_{wk} - 1} d\phi_k \\
&= \prod_{k=1}^{K} \frac{\Gamma(\Sigma_{w=1}^{J} \beta_w)}{\Sigma_{w=1}^{J} \Gamma(\beta_w)} \frac{\prod_{w=1}^{J} \Gamma(N_{wk} + \beta_w)}{\Gamma(\Sigma_{w=1}^{J} N_{wk} + \beta_w)} \int \frac{\Gamma(\Sigma_{w=1}^{J} N_{wk} + \beta_w)}{\prod_{w=1}^{J} \Gamma(N_{wk} + \beta_w)} \prod_{w=1}^{J} \phi_{kw}^{\beta_w + N_{wk} - 1} d\phi_k \\
&= \prod_{k=1}^{K} \frac{\Gamma(\Sigma_{w=1}^{J} \beta_w)}{\Sigma_{w=1}^{J} \Gamma(\beta_w)} \frac{\prod_{w=1}^{J} \Gamma(N_{wk} + \beta_w)}{\Gamma(\Sigma_{w=1}^{J} N_{wk} + \beta_w)}
\end{aligned}
$$

(b) (1 point) Exact probabilistic inference on $P(z \mid d)$ is infeasible – explain why.
sol: $P(z \mid d) = \frac{P(d \mid z) P(z)}{P(d)}$. The numerator is computed in above question. The denominator is computed as $\Sigma_z P(d \mid z) P(z)$. The summation involves integration over MN rvs (Assuming each document has N words) each taking K different values. So it is computationally hard.

(c) (5 points) Since exact inference is infeasible, we will use approximate inference. In particular, we are first interested in "collapsed" Gibbs sampling ("collapsed" since ϕ and θ are integrated out in the inference procedure). Prove the following LDA collapsed Gibbs sampling equation:

$$
p(z_{ji} = k \mid z \backslash z_{ji}, d, \alpha, \beta) \propto (N_{ki}^{(-ji)} + \alpha_k) \frac{N_{wk}^{(-ji)} + \beta_w}{N_k^{(-ji)} + \sum_{w'} \beta_{w'}}
$$

where $w = d_{ji}$.
(Hint: $\Gamma(x + 1) = x\Gamma(x)$)

sol:

$$
\begin{aligned}
p(z_{ji} \mid z \backslash z_{ji}, d, \alpha, \beta) &= \frac{p(z_{ji}, z \backslash z_{ji}, d, \alpha, \beta)}{p(z \backslash z_{ji}, d, \alpha, \beta)} \\
&\propto p(z_{ji}, z \backslash z_{ji}, d, \alpha, \beta) \\
&= p(d, z \mid \alpha, \beta) \\
&= \prod_{i=1}^{M} \frac{\Gamma(\Sigma_{k=1}^{K} \alpha_k)}{\prod_{k=1}^{K} \Gamma(\alpha_k)} \frac{\prod_{k=1}^{K} \Gamma(N_{ki} + \alpha_k)}{\Gamma(\Sigma_{k=1}^{K} N_{ki} + \alpha_k)} \prod_{k=1}^{K} \frac{\Gamma(\Sigma_{w=1}^{J} \beta_w)}{\Sigma_{w=1}^{J} \Gamma(\beta_w)} \frac{\prod_{w=1}^{J} \Gamma(N_{wk} + \beta_w)}{\Gamma(\Sigma_{w=1}^{J} N_{wk} + \beta_w)} \\
&\propto \prod_{m=1}^{M} \frac{\prod_{k=1}^{K} \Gamma(N_{km} + \alpha_k)}{\Gamma(\Sigma_{k=1}^{K} N_{km} + \alpha_k)} \prod_{k=1}^{K} \frac{\prod_{w=1}^{J} \Gamma(N_{wk} + \beta_w)}{\Gamma(\Sigma_{w=1}^{J} N_{wk} + \beta_w)}
\end{aligned}
$$

$$
\begin{aligned}
\prod_{m=1}^{M} \frac{\prod_{k=1}^{K} \Gamma(N_{km} + \alpha_k)}{\Gamma(\Sigma_{k=1}^{K} N_{km} + \alpha_k)} &= \prod_{m \neq i} \frac{\prod_{k=1}^{K} \Gamma(N_{km} + \alpha_k)}{\Gamma(\Sigma_{k=1}^{K} N_{km} + \alpha_k)} \frac{\prod_{k=1}^{K} \Gamma(N_{ki} + \alpha_k)}{\Gamma(\Sigma_{k=1}^{K} N_{ki} + \alpha_k)} \\
&\propto \frac{\prod_{k=1}^{K} \Gamma(N_{ki} + \alpha_k)}{\Gamma(\Sigma_{k=1}^{K} N_{ki} + \alpha_k)} \\
&\propto \frac{\prod_{k \neq z_{ji}} \Gamma(N_{ki}^{-ji} + \alpha_k) \times \Gamma(N_{z_{ji}i}^{-ji} + \alpha_{z_{ji}} + 1)}{\Gamma(1 + \Sigma_{k=1}^{K} N_{ki}^{-ji} + \alpha_k)} \\
&\propto \frac{\prod_{k \neq z_{ji}} \Gamma(N_{ki}^{-ji} + \alpha_k) \times \Gamma(N_{z_{ji}i}^{-ji} + \alpha_{z_{ji}}) \times (N_{z_{ji}i}^{-ji} + \alpha_{z_{ji}})}{\Gamma(1 + \Sigma_{k=1}^{K} N_{ki}^{-ji} + \alpha_k)} \\
&\propto \frac{\prod_{k=1}^{K} \Gamma(N_{ki}^{-ji} + \alpha_k) \times (N_{z_{ji}i}^{-ji} + \alpha_{z_{ji}})}{\Gamma(1 + \Sigma_{k=1}^{K} N_{ki}^{-ji} + \alpha_k)} \\
&\propto (N_{z_{ji}i}^{-ji} + \alpha_{z_{ji}})
\end{aligned}
$$

$$\prod_{k=1}^{K} \frac{\prod_{w=1}^{J} \Gamma(N_{wk} + \beta_w)}{\Gamma(\Sigma_{w=1}^{J} N_{wk} + \beta_w)} = \prod_{k=1}^{K} \frac{\prod_{w \neq d_{ji}} \Gamma(N_{wk} + \beta_w) \Gamma(N_{d_{ji}k} + \beta_{d_{ji}})}{\Gamma(\Sigma_{w=1}^{J} N_{wk} + \beta_w)}$$

$$\propto \prod_{k=1}^{K} \frac{\Gamma(N_{d_{ji}k} + \beta_{d_{ji}})}{\Gamma(\Sigma_{w=1}^{J} N_{wk} + \beta_w)}$$

$$\propto \prod_{k \neq z_{ji}} \frac{\Gamma(N^{-ji}_{d_{ji}k} + \beta_{d_{ji}})}{\Gamma(\Sigma_{w=1}^{J} N_{wk} + \beta_w)} \times \frac{\Gamma(N^{-ji}_{d_{ji}z_{ji}} + \beta_{d_{ji}} + 1)}{\Gamma(1 + \Sigma_{w=1}^{J} N^{-ji}_{wz_{ji}} + \beta_w)}$$

$$\propto \prod_{k \neq z_{ji}} \frac{\Gamma(N^{-ji}_{d_{ji}k} + \beta_{d_{ji}})}{\Gamma(\Sigma_{w=1}^{J} N_{wk} + \beta_w)} \times \frac{\Gamma(N^{-ji}_{d_{ji}z_{ji}} + \beta_{d_{ji}}) \times (N^{-ji}_{d_{ji}z_{ji}} + \beta_{d_{ji}})}{\Gamma(\Sigma_{w=1}^{J} N^{-ji}_{wz_{ji}} + \beta_w) \times (\Sigma_{w=1}^{J} N^{-ji}_{wz_{ji}} + \beta_w)}$$

$$\propto \prod_{k=1}^{K} \frac{\Gamma(N^{-ji}_{d_{ji}k} + \beta_{d_{ji}})}{\Gamma(\Sigma_{w=1}^{J} N_{wk} + \beta_w)} \times \frac{(N^{-ji}_{d_{ji}z_{ji}} + \beta_{d_{ji}})}{(\Sigma_{w=1}^{J} N^{-ji}_{wz_{ji}} + \beta_w)}$$

$$\propto \frac{(N^{-ji}_{d_{ji}z_{ji}} + \beta_{d_{ji}})}{(\Sigma_{w=1}^{J} N^{-ji}_{wz_{ji}} + \beta_w)}$$

$$p(z_{ji} \mid z \backslash z_{ji}, d, \alpha, \beta) \propto (N^{-ji}_{z_{ji}i} + \alpha_{z_{ji}}) \times \frac{(N^{-ji}_{d_{ji}z_{ji}} + \beta_{d_{ji}})}{(\Sigma_{w=1}^{J} N^{-ji}_{wz_{ji}} + \beta_w)}$$

$$= (N^{-ji}_{z_{ji}i} + \alpha_{z_{ji}}) \times \frac{(N^{-ji}_{d_{ji}z_{ji}} + \beta_{d_{ji}})}{(N^{-ji}_{z_{ji}} + \Sigma_{w=1}^{J} \beta_w)}$$

for $z_{ji} = k$ and $d_{ji} = w$ we get

$$p(z_{ji} = k \mid z \backslash z_{ji}, d, \alpha, \beta) \propto (N^{-ji}_{ki} + \alpha_k) \times \frac{(N^{-ji}_{wk} + \beta_w)}{(N^{-ji}_{k} + \Sigma_{w'=1}^{J} \beta_{w'})}$$

(d) (5 points) As an alternate approximate inference approach, we will use a variational method (in particular, Naïve Mean Field or NMF, again "(θ, ϕ)-collapsed") that approximates $P(z \mid d)$ using a fully factored distbn.:

$$Q(z \mid \lambda) = \prod_i \prod_j Q_{ji}(z_{ji} \mid \lambda_{ji}),$$

where $Q(z_{ji} = k \mid \lambda) = Q_{ji}(z_{ji} = k \mid \lambda_{ji}) := \lambda_{jik}$. The free variational parameters $\lambda = \{\lambda_{jik}\}$ that minimizes the KL-divergence $D(Q \,||\, P)$ can be heuristically found using an iterative fixed-point

NMF theorem seen in class. Apply this theorem to derive this NMF update rule:

$$Q_{ji}(z_{ji} = k) := \lambda_{jik} \quad \propto \quad (E_{Q_{-ji}}[N_{ki}^{(-ji)}] + \alpha_k) \frac{E_{Q_{-ji}}[N_{wk}^{(-ji)}] + \beta_w}{E_{Q_{-ji}}[N_k^{(-ji)}] + \sum_{w'} \beta_{w'}}$$

where $w = d_{ji}$ and Q_{-ji} refers to the (fully-factored) distribution over all z variables other than z_{ji} using the current iteration settings of all λ parameters other than λ_{jik}.
(Hint: You may use, $\log \frac{\Gamma(x+q)}{\Gamma(x)} = \sum_{p=0}^{q-1} \log(x+p)$, for real $x > 0$ and integer $q > 0$; and a crude approximation, $E[\log(X)] \simeq \log(E[X])$.)
sol: from NMF theorem, we have

$$\begin{aligned}
Q(z_{ji}) &\propto \exp\left(E_Q[\ln(p(z, d)) \mid z_{ji} = k]\right) \\
&\propto \exp\left(E_Q[\ln(p(z \mid d)) \mid z_{ji} = k]\right) \\
&\propto \exp\left(E_Q[\ln(p(z_{ji} \mid z \backslash z_{ji}, d) p(z \backslash z_{ji} \mid d)) \mid z_{ji} = k]\right) \\

\end{aligned}$$

(e) (0 points) *(Optional Intuition/Background Question)* A key inference query in a latent model like LDA is the conditional (posterior) probability of the hidden variables, viz., $P(z, \theta, \phi \mid d, \alpha, \beta)$, but we focused only on the "(θ, ϕ)-collapsed" probability $P(z \mid d, \alpha, \beta)$ so far, since collapsed approximate inference (collapsed Gibbs sampling or collapsed variational inference) methods are often more accurate than full (non-collapsed) approximate inference. Furthermore, once we've information on z, we can get information about (θ, ϕ) as described below.

Estimation of θ_i (document-topic proportion) and ϕ_k (topic-word distribution) are greatly simplified by knowing z_{ji} (topic assignment for each word d_{ji} in document i, drawn from $P(z \mid d)$ given by the collapsed Gibbs sampler above or from $Q(z)$ given by the collapsed variational method above). **Write down the most intuitive formula you can think for estimating $\theta_i = \{\theta_{ik}\}$ and $\phi_k = \{\phi_{kw}\}$ from all z_{ji}.** Argue why these intuitive point estimates are in fact the posterior mean of θ_i and ϕ_k (the posterior here refers to the conditional distribution $(\theta_i \mid z, d)$

or equivalently $(\theta_i \mid z)$ for θ_i, and a similar conditional distribution $(\phi_k \mid z, d)$ for ϕ_k)).
sol:
we know z_{ji} for all the words in all the documents. For constructing ϕ_k we take all the words falling in topic k ie words with $z_{ji} = k$ and construct an empirical distribution out of it ie ϕ_{kw} will be normalized count of word w falling in topic k.
For constructing θ_i we take document i and find the count of words for each topic k and take normalized count of each topic to be θ_{ik}
Generally learning will be in a way that empirical mean and model mean are made equal. So, the above point empirical estimates are model(posterior) mean.

(Note: Drawing the graph structure of all three models in this assignment can aid your intuition; you can use a grid-graph for image denoising, a complete bipartite graph for RBM, and a plate network diagram for LDA.)
